

Need help with VMware Configuration.

I have installed VMWare trial and have a Virtual Machine Running.

Everythings works except it's somewhat slow and the VM freeze when inactive.

When I go to my main OS for more than 10 min then I toggle back to VMware the VM has frozen.

What are the first things I would need to investigate in order to get more speed from my VM and resolve the freezing problem?

Thanks for the help!

David,

Could you describe your environment a little? What hardware are you running on? RAM, CPU, Hard disk space/type. What OS are you running under VMware? What Version of VMware are you running, is it workstation, Fusion, vmware server, esxi?
